Generalizing Patterns: Table Tiles
Generalizing Patterns: Table Tiles

MATHEMATICAL GOALS
This lesson unit is intended to help you assess how well students are able to identify linear and quadratic relationships in a realistic context: the number of tiles of different types needed for a range of square tabletops. In particular, this unit aims to identify and help students who have difficulties:

- Choosing an appropriate, systematic way to collect and organize data.
- Examining the data and looking for patterns; finding invariance and covariance in the numbers of different types of tile.
- Generalizing using numerical, geometrical or algebraic structure.
- Describing and explaining findings clearly and effectively.

COMMON CORE STATE STANDARDS
This lesson relates to all the Standards for Mathematical Practices in the Common Core State Standards for Mathematics, with a particular emphasis on Practices 1, 2, 3, 4, 7, and 8:

1. Make sense of problems and persevere in solving them.
2. Reason abstractly and quantitatively.
3. Construct viable arguments and critique the reasoning of others.
4. Model with mathematics.
5. Use appropriate tools strategically.
6. Attend to precision.
7. Look for and make use of structure.
8. Look for and make use of repeated reasoning.

This lesson gives students the opportunity to apply their knowledge of the following Standards for Mathematical Content in the Common Core State Standards for Mathematics:

F-BF: Build a function that models a relationship between two quantities.

INTRODUCTION
The unit is structured in the following way:

- Before the lesson, students attempt the task individually. You then review their work and formulate questions for students to answer in order for them to improve their work.
- At the start of the lesson, students work individually to answer your questions.
- Next, they work collaboratively, in small groups, to produce a better joint solution than those they produced alone. In the same small groups, students critique examples of other students’ work.
- In a whole-class discussion, students explain and compare the approaches seen and used.
- Finally, students reflect on their work and their learning.

MATERIALS REQUIRED

- Each student will need the Table Tiles task, a copy of the Grid Paper and a copy of the How Did You Work? questionnaire.
- Each small group of students will need a copy of the Grid Paper and the Sample Responses to Discuss.
- There is a projector resource to help you with the whole-class discussions.

TIME NEEDED:
15 minutes before the lesson, a 1-hour lesson, and 10 minutes in a follow-up lesson. All timings are approximate. Exact timings will depend on the needs of the class.
BEFORE THE LESSON

Assessment task: Table Tiles (15 minutes)

Have the students do this task in class or for homework a day or more before the formative assessment lesson. This will give you an opportunity to assess the work and to find out the kinds of difficulties students have with it. You should then be able to target your help more effectively in the subsequent lesson.

Give each student a copy of Table Tiles and a copy of the Grid Paper. Introduce the task briefly and help the class to understand what they are being asked to do:

Spend 15 minutes on your own, answering these questions.

Show your work on the worksheet and the grid paper.

Don’t worry if you can’t do everything. There will be a lesson on this material [tomorrow] that will help you improve your work. Your goal is to be able to answer these questions with confidence by the end of that lesson.

It is important that, as far as possible, students answer the questions without assistance.

Students who sit together often produce similar answers so that when they come to compare their work, they have little to discuss. For this reason, we suggest that when students do the task individually you ask them to move to different seats. Then, at the beginning of the formative assessment lesson, allow them to return to their usual places. Experience has shown that this produces more profitable discussions.

Assessing students’ responses

Collect students’ responses to the task. Make some notes on what their work reveals about their current levels of understanding and their different problem solving approaches. The purpose of this is to forewarn you of the issues that will arise during the lesson, so that you may prepare carefully.

We suggest that you do not score students’ work. Research shows that this is counterproductive, as it encourages students to compare scores and distracts their attention from how they may improve their mathematics.

Instead, help students to make further progress by asking questions that focus attention on aspects of their work. Some suggestions for these are given in the Common issues table on the next page(s). These have been drawn from common difficulties observed in trials of this unit.

We suggest you make a list of your own questions, based on your students’ work. We recommend you either:

• write one or two questions on each student’s work, or
• give each student a printed version of your list of questions and highlight the questions for each individual student.
If you do not have time to do this, you could select a few questions that will be of help to the majority of students and write these on the board when you return the work to the students at the beginning of the lesson.

<table>
<thead>
<tr>
<th>Common issues</th>
<th>Suggested questions and prompts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Makes unintended assumptions</td>
<td>• Imagine you can buy tiles that are ready cut. You don’t need to cut them up. How many of each type do you need?</td>
</tr>
<tr>
<td>For example: The student has calculated the number of whole tiles required to cover the tabletop, assuming tiles can be split to make quarters and halves. Or: The student uses only quarter tiles to cover the tabletop.</td>
<td></td>
</tr>
<tr>
<td>Makes inaccurate drawing</td>
<td>• How would you describe how to draw a 30 cm by 30 cm tabletop?</td>
</tr>
<tr>
<td>For example: The student divides the whole tabletop into ‘units’ of a whole tile surrounded by four, quarter tiles. Or: The student draws freehand with a different number of half tiles along each side.</td>
<td></td>
</tr>
<tr>
<td>Assumes proportionality</td>
<td>• Read the rubric. Where does Maria use quarter tiles? Half tiles? • What happens to tiles in the middle of the diagram if you extend the size?</td>
</tr>
<tr>
<td>For example: The student writes ‘10 whole tiles, 8 half tiles, 8 quarter tiles.’ (Q1) The student believes a tabletop with sides twice as long will need twice as many tiles of each type.</td>
<td></td>
</tr>
<tr>
<td>Produces unsystematic work</td>
<td>• Which example will you draw next? Why? • What do you notice about the difference between the number of whole tiles in one tabletop and the next? • The sizes of square tabletops are all multiples of 10 cm. Do your diagrams show this?</td>
</tr>
<tr>
<td>For example: The student draws seemingly unconnected examples, such as 10 cm by 10 cm or 40 cm by 40 cm. Or: The student omits some diagrams, drawing tabletops that are 20 cm by 20 cm and 40 cm by 40 cm, but not 30 cm by 30 cm.</td>
<td></td>
</tr>
<tr>
<td>Does not generalize</td>
<td>• Can you describe a visual pattern in the number of whole tiles in consecutive diagrams? • How could I find out the number of tiles needed for a larger tabletop, without having to continue the pattern?</td>
</tr>
<tr>
<td>For example: The student does not know how to proceed with finding the quadratic expression. Or: The student identifies patterns in the numbers of different types of tiles but does not extend to the general case.</td>
<td></td>
</tr>
<tr>
<td>Writes answers without explanation</td>
<td>• How could you explain how you reached your conclusions so that someone in another class understands?</td>

</table>
**SUGGESTED LESSON OUTLINE**

**Improve individual solutions to the assessment task (10 minutes)**

Return your students’ work on the *Table Tiles* task. Ask students to re-read both the *Table Tiles* problem and their solutions. If you have not added questions to students’ work, write a short list of your most common questions on the board. Students can then select a few questions appropriate to their own work and begin answering them.

*Recall what we were working on previously. What was the task?*

Draw students’ attention to the questions you have written.

*I read your solutions and have some questions about your work.*

*I would like you to work on your own for 10 minutes to answer my questions.*

Students can either make a note of their answers to your questions on the back of their scripts or on a fresh piece of paper.

**Collaborative small-group work (15 minutes)**

Organize the students into small groups of two or three. In trials, teachers found keeping groups small helped more students play an active role. Give each group a new sheet of *Grid Paper*.

Students should now work together to produce a joint solution.

*Put your individual solutions aside. I want you to work in groups now.*

*Your task is to work together to produce a solution that is better than your individual solutions.*

You have two tasks during small-group work: to note different student approaches to the task and to support student problem solving.

**Note different student approaches to the task**

Notice how students work on finding the quadratic function for the number of whole tiles. Notice also whether and when students introduce algebra. If they do use algebra, note the different formulations of the functions they produce, including incorrect versions. You can use this information to focus the whole-class discussion towards the end of the lesson.

**Support student problem solving**

Try not to make suggestions that move students towards a particular approach to this task. Instead, ask questions to help students clarify their thinking. If several students in the class are struggling with the same issue, you could write a relevant question on the board. You might also ask a student who has performed well on one part of the task to help a student struggling with that part of the task.

The following questions and prompts have been found most helpful in trials:

*What information have you been given?*

*What do you need to find out?*

*What changes between these diagrams? What stays the same?*

*What if I wanted to know the thousandth example?*

*How will you write down your pattern?*

*Why do you think your conjecture might be true?*

In trials, teachers expressed surprise at the degree of difficulty some students experienced in drawing the tabletops. If this issue arises in your class, help the student to focus his or her attention on
different parts of the tabletop, how they align with the grid and then get them to draw the whole
diagram from those pieces.

Where are the half tiles? Whole tiles?
How do the whole and half tiles fit together?

You may find that some students do not work systematically when drawing tabletops and organizing their data.

What sizes of tabletop might Maria make? Which ones is it useful for you to draw? Why?
What can you do to organize your data?

If students have found formulas, focus their attention on improving explanations, exploring
alternative methods, and showing the equivalence of different equations.

How can you be sure your explanation works in all cases?
Ask another group if your argument makes sense.
Which is the formula you prefer? Why?
Show me that these two expressions are equivalent.

Students may justify their formulas by drawing another example to see if the generalization fits a new case, reasoning inductively. Some stronger explanations are shown in the Sample Responses to Discuss.

Collaborative analysis of Sample Responses to Discuss (15 minutes)

Give each small group of students a copy of the Sample Responses to Discuss. These are three of the common problem-solving approaches taken by students in trials. Display the following questions on the board or project Slide P-2 Sample Responses to Discuss.

Describe the problem solving approach the student used.

You might, for example:

- Describe the way the student has colored the pattern of tiles.
- Describe what the student did to calculate a sequence of numbers.

Explain what the student needs to do to complete his or her solution.

This analysis task will give students an opportunity to evaluate a variety of alternative approaches to the task, without providing a complete solution strategy.

During small-group work, support student thinking as before. Also, check to see which of the explanations students find more difficult to understand. Identify one or two of these approaches to discuss in the whole-class discussion. Note similarities and differences between the sample approaches and those the students took during the collaborative small-group work.

Leon drew three diagrams showing tabletops with systematically increasing side lengths. He colored the diagrams to pick out rows of whole squares parallel to the diagonal of the tabletop.

<table>
<thead>
<tr>
<th>Width of tabletop</th>
<th>10 cm</th>
<th>20 cm</th>
<th>30 cm</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of whole tiles</td>
<td>1</td>
<td>1 + 3 + 1</td>
<td>1 + 3 + 5 + 3 + 1</td>
</tr>
</tbody>
</table>
Leon wrote the sum of the numbers to show the total number of whole tiles. He did this in an organized way. He predicted the number of whole tiles in the next diagram accurately.

Leon could check the next diagram to see if his conjecture is correct, but this would not be a proof. He could use his method to predict the number of whole tiles in the next diagram for any diagram he has drawn, but that method would not enable him to calculate the number of whole tiles for tables of any size. To do that, he might attempt to articulate the relationship between the number of whole tiles across the diagonal and the number of odd numbers to sum (assuming that students do not recognize that $1 + 3 + 5 + \ldots + 2n - 1 = n^2$).

**Gianna** shaded alternate horizontal rows of squares. In the first two diagrams she wrote numbers in the whole squares. These record the number of whole squares in each horizontal row of that tabletop.

For the diagram of the 30 cm tabletop this gives:

In the first row: 3 3 3
In the second row: 2 2
In the third row: 3 3 3
In the fourth row: 2 2
In the fifth row: 3 3 3

Gianna picked out the pattern as 3 rows of 3 whole tiles, and 2 rows of 2 whole tiles, to find the total number of whole tiles is $3 \times 3 + 2 \times 2$.

Gianna could then generalize to show that in the $n^{th}$ tabletop there would be $n$ rows of $n$ whole tiles, and $n - 1$ rows of $n - 1$ whole tiles, in total $n^2 + (n - 1)^2$ whole tiles.

**Ava** drew one diagram showing how the length of a 40 cm tabletop is made of two 5 cm edges of quarter tiles and three 10cm half tiles, and another similar diagram for the 50 cm table. Ava systematically organized data in a table, although it is not clear where the data came from. She found differences and second differences between numbers of tiles in tables of increasing side length. She did not show a way of calculating the number of tiles of various types given an arbitrary table size and she did not use algebra.

Ava could next use her table of data to derive formulas for the number of tiles in any table. She might do this by using the first and second differences with the standard quadratic sequence algorithm.
**Whole-class discussion: comparing different approaches (20 minutes)**

Organize a whole-class discussion to consider different approaches to the task. The intention is for you to focus on getting students to understand the methods of working out the answers, rather than either numerical or algebraic solutions. Focus your discussion on parts of the two small-group tasks students found difficult. You may find it helpful to display Slide P-3 Grid Paper, or Slide P-4 Tabletops.

*Let’s stop and talk about different approaches.*

Ask the students to compare the different solution methods.

- *Which approach did you like best? Why?*
- *Which approach did you find it most difficult to understand?*
- *Sami, your group used that method. Can you explain that for us?*
- *Which method would work best for the thousandth tabletop?*

Below, we have given details of some discussions that emerged in trial lessons.

Some students found the work on quadratic expressions very difficult. If your students have this problem, you might focus on Gianna’s method from the Sample Responses to Discuss (Slide P-6).

*Describe Gianna’s pattern in the whole tiles in the 30 cm by 30 cm tabletop.*

*How would you describe her pattern in the next size tabletop?*

*Using Gianna’s pattern, how many whole tiles would there be in any tabletop?*

If students have found different algebraic formulations for the number of half and whole tiles, it might help to write a variety of their expressions on the board. Ask students to link different variables and manipulate algebraic expressions to identify errors and show equivalences:

- *Which of these formulas would you use to find the number of half tiles?*
- *Which are quadratic?*
- *Are there any formulas that are equivalent?*

**Follow-up lesson: individual reflection (10 minutes)**

Give each student a copy of the *How Did You Work?* questionnaire.

*Think carefully about your work on this task and the different methods you have seen and used.*

*On your own, answer the review questions as carefully as you can.*

Some teachers give this as a homework task.

</tbody>
</table>

Let the side of a tabletop be $x \text{ cm}$ by $x \text{ cm}$.

Since these are multiples of 10, we can simplify the algebra if we let $n = \frac{x}{10}$.

The number of quarter tiles is always 4.

The number of half tiles is $4(n - 1) = 4\left(\frac{x}{10} - 1\right)$.

The number of whole tiles is $n^2 + (n - 1)^2 = 2n^2 - 2n + 1 = 2\left(\frac{x}{10}\right)^2 - 2\left(\frac{x}{10}\right) + 1 = \frac{x^2}{50} - \frac{x}{5} + 1$. 
Table Tiles

Maria makes tables with square tops. She sticks tiles to the top of each table.

Maria uses three types of tiles:

- whole tiles
- half tiles
- quarter tiles

The sizes of the square tabletops are all multiples of 10 cm. Maria only uses quarter tiles in the corners and half tiles along the edges of the table.

Here is one tabletop:

This square tabletop uses: 5 whole tiles, 4 half tiles, 4 quarter tiles.

1. How many tiles of each type will she need for a 40 cm by 40 cm square?

2. Describe a method for calculating how many tiles of each type Maria needs for larger square tabletops.
Grid Paper
Sample Responses to Discuss

Here is some work on Table Tiles from three students in another class: Leon, Gianna, and Ava. For each piece of work:

1. Describe the problem solving approach the student used.
   For example, you might:
   - Describe the way the student has colored the pattern of tiles.
   - Describe what the student did to calculate a sequence of numbers.

2. Explain what the student needs to do to complete his or her solution.

Leon's method
Gianna’s method
How Did You Work?

1. In what ways was the method that your group used similar and/or different to the methods shown in the sample responses?

<table>

<tr>
<td>Ava</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Which method do you think would be the most efficient method for determining the number of each type of tile required for a table with dimensions 100 cm by 100 cm? Explain your answer.

3. Of the methods shown in the sample responses, which method do you think is the clearest and easiest to understand? Explain why.

4. Which of the methods shown in the sample responses leads more easily towards establishing a general rule for determining the numbers of each type of tile required for any size table? Explain why.
Maria makes tables with square tops. She sticks tiles to the top of each table.

Maria uses three types of tiles:

- whole tiles
- half tiles
- quarter tiles

The sizes of the square tabletops are all multiples of 10 cm. Maria only uses quarter tiles in the corners and half tiles along the edges of the table.

Here is one tabletop:

This square tabletop uses:
5 whole tiles, 4 half tiles, 4 quarter tiles.
1. Describe the problem solving approach the student used.
   You might, for example:
   • Describe the way the student has colored the pattern of tiles.
   • Describe what the student did to calculate a sequence of numbers.

2. Explain what the student needs to do to complete his or her solution.

Mathematics Assessment Project

Classroom Challenges

These materials were designed and developed by the Shell Center Team at the Center for Research in Mathematical Education University of Nottingham, England:

Malcolm Swan,
Nichola Clarke, Clare Dawson, Sheila Evans, Colin Foster, and Marie Joubert
with
Hugh Burkhardt, Rita Crust, Andy Noyes, and Daniel Pead

We are grateful to the many teachers and students, in the UK and the US, who took part in the classroom trials that played a critical role in developing these materials

The classroom observation teams in the US were led by
David Foster, Mary Bouck, and Diane Schaefer

This project was conceived and directed for
The Mathematics Assessment Resource Service (MARS) by
Alan Schoenfeld at the University of California, Berkeley, and
Hugh Burkhardt, Daniel Pead, and Malcolm Swan at the University of Nottingham

Thanks also to Mat Crosier, Anne Floyde, Michael Galan, Judith Mills, Nick Orchard, and Alvaro Villanueva who contributed to the design and production of these materials

This development would not have been possible without the support of
Bill & Melinda Gates Foundation

We are particularly grateful to
Carina Wong, Melissa Chabran, and Jamie McKee
